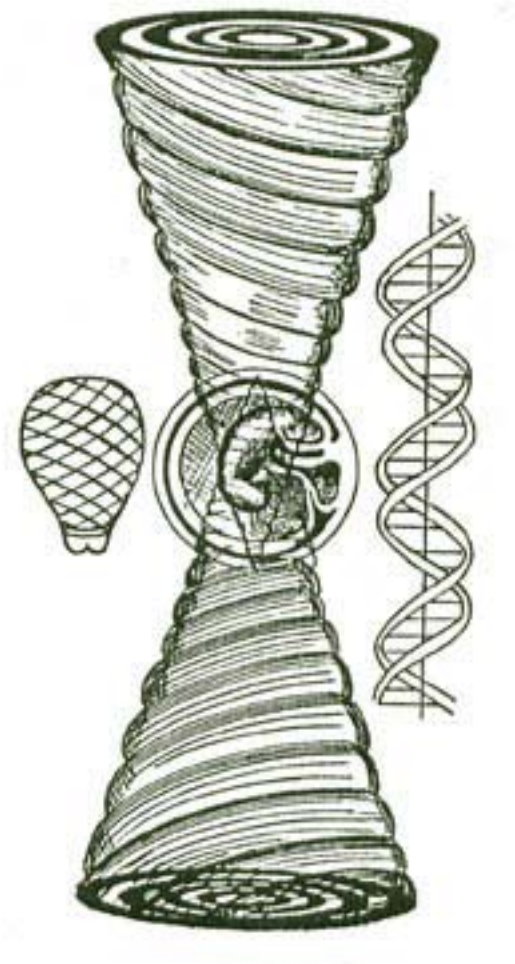
Vortex Mechanics and Your Health

The mechanics of a Universal phenomenon-the vortex, are operative and vital in all biological organisms. This comparison of Human Blood and the 'blood of the Earth'—Water, shows us Nature's applications of vortex mechanics in these precious organisms.

Upon the union of the male and female forces (two opposites approaching each other) the archetypal phenomena of vortex formation comes into existence. At the surfaces of contact there is a tendency for one layer to roll in upon the other and form an eddy, just like when two oppositely approaching water streams meet—an eddy or vortex womb is formed. This is the formative process.

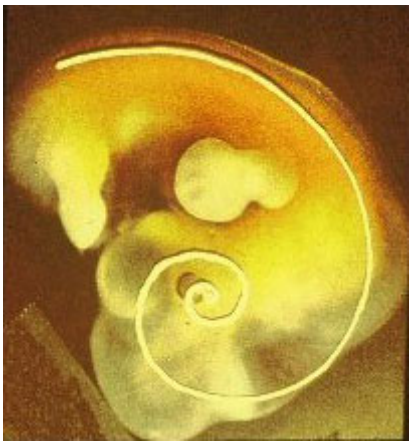
Every living creature and every physical form comes forth from its invisible idea to its visible form via the archetypal swirling action of the vortex.
An observation in action is the formation and growth of an embryo. The vortexian process, swirling and curling provides the invaginating process for the development of bodily transportation systems, limbs, organs and the most sensitive details of brain and consciousness. The spiraling process encircles, defines, feeds and forms the embryo with a liquid whether in the mammalian egg-shaped uterus or the eggs of insects, birds or reptiles.



Growth of the fetus follows vortexian laws. We can note the spiral growth of the spine and the spiral pattern of the pituitary gland above and behind the

eyes at the base of the cranium. The pituitary gland is the Master Gland that controls the rate of growth of a body.

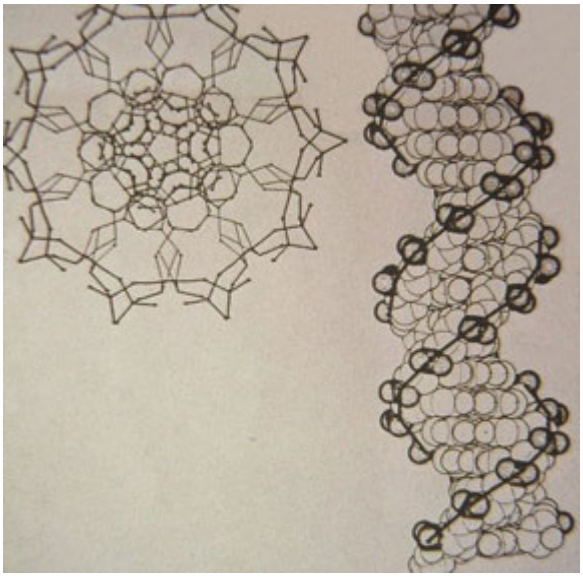
Human Fetus

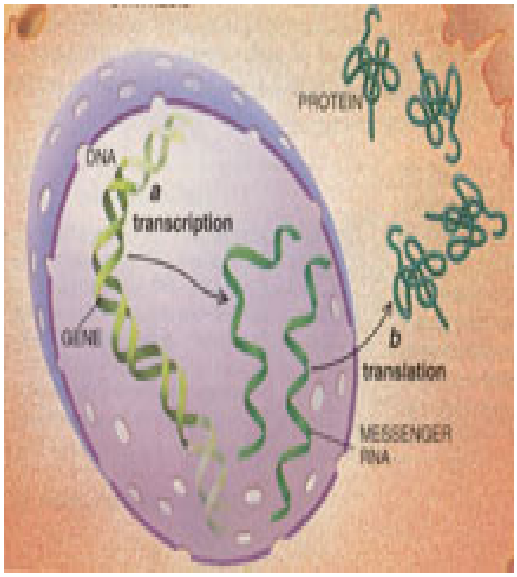


Fish Fetus

Examination of the muscles of the uterus shows us the importance of vortexian motion in the function of birth. Layers of spiraling muscles from the top to cervix insure the ability of this organ to expand without rupture and contract at birth in a rhythmical pattern from base toward the apex (cervix) to deliver a longitudinal force to push the baby out into the world.

The arteries of the uterus are winding and spiralic also, to insure one last life-supporting centripetal twisting impetus to the blood feeding a new life.



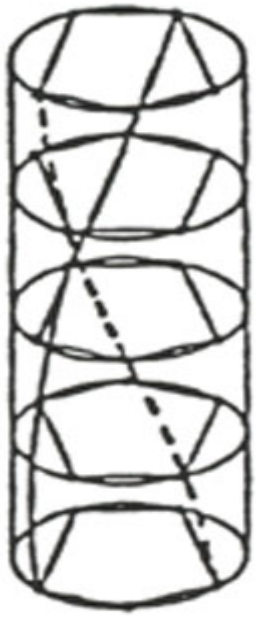


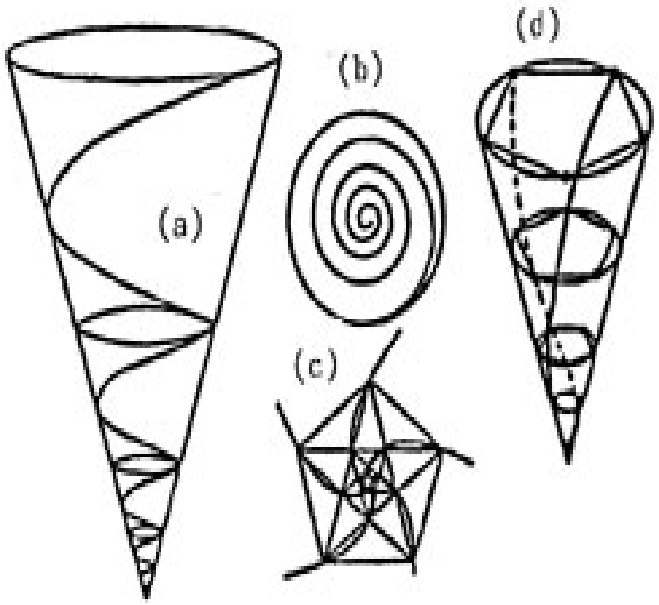
The Blueprint of Life

The Science of Genetics tells us that all the blueprint of life is stored in the spiral and helical formations of the DNA molecules. The vortex not only

serves as a dynamic motion body to deliver power, but also acts as a record and messenger to give instructions for the construction and building process.

Recent research into the structure of DNA shows it to be a geometric pattern best described as a helical extension of rotating pentagonal nests of molecules.





Another interesting discovery in relation to Vortexian Mechanics is that the usually observed cylindrical form of DNA is only the structure at rest. Whenever a growth process occurs the cylinder becomes a conical spiral, contracting with an inward motion (centripetal) toward an apex , which generates new life.

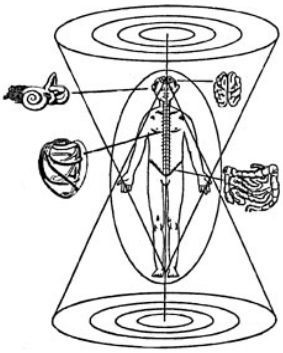
A growing process can be shown by a spiral in a cone (a), that looked at from the top down is a simple logarithmic spiral (b). A pentagon whose sides are extended out as shown in (c) will produce five more points that can be joined to create a larger pentagon. (See "Teachers & Students" to get a template for this blueprint)

Each of the larger pentagons produced in this way is rotated 1/1oth of a full circle. Looking from the top down, it would be a series of pentagons, getting larger, each one rotated 1/1oth of a circle from the previous one (d).

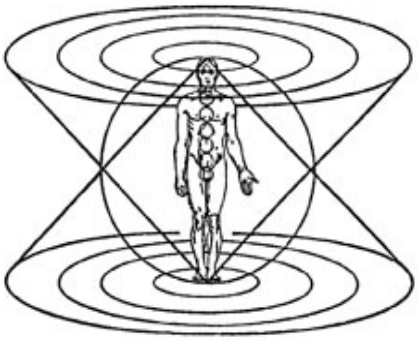
This ‘working’ form of the DNA occurs when it is accomplishing action. The conical form then reconverts into the cylindrical form usually modeling DNA.

Vortex Growth

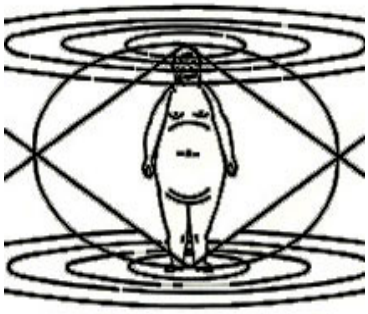
The two main vortices that united to birth a new body, and that represent the main energy accumulators for growth, development and sustenance of that body, are growing changing energy forms. At the early stage of vortex union, both vortices are long and slender and their area of union is represented by a long slender shape where they overlap. Their sphere of manifestation is a slender, prolated oval. The growth shows this slender form during early stages. The body of the child is polarizing longitudinally, muscles and limbs are growing in length more than width and a young person is lean and tall.



Youth



Maturity



Aging

At this early stage of vortex development the inward, generating centripetal force is preponderant. The vortices are charging, more than discharging, the new body with life supporting energy, and growth is increasing.

As the vortices reach maturity they draw into each other more and reach a shape of more balanced proportions. In the drawing we see a mature person within the cube and a perfect sphere formation.

The next stage of both the vortex energy bodies and the human body is that of aging. The earlier slender vortices, with a predominantly centripetal force, now lose their strength, become wider and sloppy, they wobble on the axis as it loses its momentum of spin; until finally their charging generating force is overpowered by the discharging, dissipating force (centrifugal). This de-generating influence upon the aging human body can be seen as the radial expansion that occurs around the middle during aging. The sphere of manifestation in the picture becomes squatted or oblate.

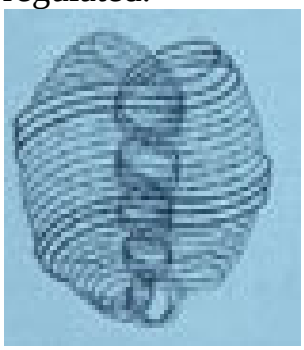
The whole cycle of birth, growth, maturity, aging and finally death in the body is parallel with the same process in ANY wave formation, whether it be the body of a sun or planet or a body of sound.

Human Anatomy

Further examination of the human anatomy shows us again the archetypal vortexian influence. Spiral growth can be seen in the fiber structure of our bones, muscles, joints and the organization and function of the heart and auricle canals. Vortices form the sense organs of the body in pairs. Clockwise and counterclockwise, they form our eyes, ears and glands for both sides of the body. The spiral convolutions of the brain and spiral fibers of the nerves indicate to us that the very thought process is a rhythmical electrical wave formation and is vortex regulated.

Brain

Cochlea



Heart

Lung

Ear

The sense organ with which we can perceive something of the inner nature of things, the ear, retreats from our observation deep[into the interior space of a funnel. An extremely delicate structure, it lies, surrounded and filled with fluid, in a cave of the hardest rock, like the spiral shell of a snail, which has secreted hard substance around itself as a protection.

Together with the neighboring semi-circular canals, this organ is one of the most sensitive in our whole organism. The ears' vortex funnel retreats to the inner ear or cochlea.

The cochlea is a structure intersecting itself three times with spiral configurations. It is built into man, giving him the capacity to hold himself erect, to balance and to move and experience himself in space. The vortex molds a perfect, most delicately differentiated sense organ.

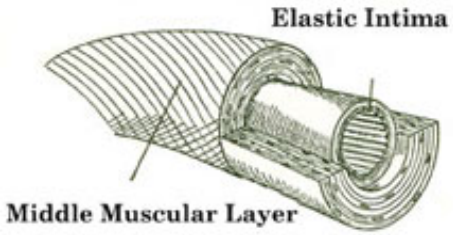
Heart
The heart pattern resembles that made when a stream of liquid flows into still water, or when streams of liquid meet under water. The whole function and form of the hearth is a reflection of the streaming, spiraling process of liquids. This organ is like a vortical center of suction to which the blood rushes with ever increasing speed from the periphery, to return again, slowing down and spreading out. It is an image of a planetary system.

A vortex pulsates in itself. Keeping strict rhythm, it widens, growing shorter, then contracts, growing longer. In the heart, the movements, superimposed on one another, result in the formation of the separate chambers. The fibers of the heart are a physical echo of the creative movements by which it was begotten. In spiraling paths they swing down to its apex and then rise again to its base. The muscles growth pattern resembles the revolving, streaming vortices of the fluids within the heart.

Digestive System
The structure and function of our digestive and circulatory systems are based on vortexian mechanics. The tubes that are our intestinal tract are not like straight cylindrical water pipes; but, have spiral muscle fibers arranged in a way to perform a centripetal compression and a centrifugal expansion alternately, to provide a peristaltic action for transportation of food and fluids.

Energy Fields
Those of metaphysical studies know the charkas of the body and aura as our energy tunnels, absorbing energy from the environment. Seers of many spiritual persuasions have described this energy inflow as spirals entering at these points. Pictures often show “discs’ very similar to discs on Twister Pipes.

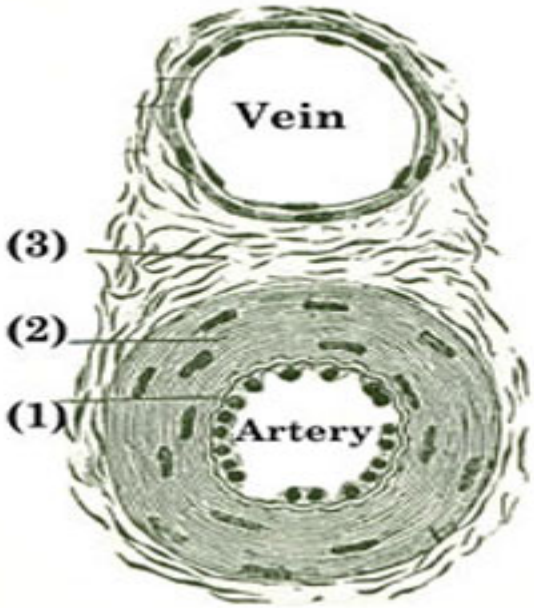
Circulation System
Look now at some of the most fragile, yet most vital structures of the body- the arteries, veins and capillaries and see the significance of vortex action in their structure and function.



The arteries and veins are composed of three coats:

1. Internal or endothelial coat
2. Middle muscular coat
3. External connective tissue

The inner coat consists of a layer of cells that can be seen in the picture by their distinct nuclei.
Underneath the endothelium is a wavy elastic intima that, on account of its delicacy, is seen as a mere line on the vein. The cells of the endothelial coat are arranged in a corrugated fashion, spiraling longitudinally. It looks like spiraling wrinkles.



The middle muscular layer consists of groups of muscles of contractile fiber cells that spiral longitudinally along the vessel. The picture shows how this layer is much more pronounced in the arteries than in veins. This thick spiral muscle layer of the arteries is necessarily more functional. The pulsing centripetal action of compression toward the inside of this arterial muscular layer aids peristaltic action of the vessels to insure longitudinal flow and maintenance of the life energy that the arterial blood must deliver. The flow of the blood is in a vortexian spiral fashion, the same as the flow of natural water courses. (See Vortex Store for "Characteristics of Water" CD)

The predominantly centripetal action in the arteries causes the compression of the elastic intima and the endothelial layer giving it a thicker appearance

and giving the inner cell and nuclei a well formed form spherical appearance. The corrugated spiraling wrinkles of the inner layer help guide the blood flow into the vortex twist.

Whereas, in a vein there is predominantly centrifugal pressure, which is radial toward the periphery, and less longitudinal force: thus, we see a wide open inner cavity, a thinned out intima and pressure on the endothelial cell and nuclei, resulting in the flattened, oblated spots in the picture. Because of the predominance of centrifugal force in the veins, the venous blood has less life energy. It is on its way back to the vortical suction within the heart to replenish.

Importance of Centripetal Predominance Within

The characteristics of centripetal motion are generative and regenerative. The effects are contraction, cooling, alkalinity, absorbing, charging, high electrical potential, amorphic structures and a sub-pressure or vacuum, to name just a few.

The characteristics of centrifugal motion are de-generating, decomposing and expanding, with just the opposite effects of heating, acidity, emanation, discharging, lowered electrical potential, crystalline formation and excessive pressure.

The blood is highly affected by excessive heat and pressure. Red corpuscles change their shape, swell up, become eccentric and even rupture their envelope under pressure. When blood is removed from the body and exposed to light, heat or atmospheric pressures, it crystallizes. The red corpuscles normally have no problem with movement, staying in a continuous flow through the vessels, with no tendency to adhere to each other or to the wall of the vessel. But, when the blood is drawn out, examined on a slide, exposed to oxygen, heat or reagents the corpuscles collect into heaps. It is suggested that this is due to an alteration in surface tension. Also exposure to heat causes blood to acidify. Healthiest blood is slightly alkaline. Blood has a certain range of requirements it must function within to stay healthy.

The vortex movement of blood is vital to its health. It keeps the ionic components of the blood suspended in an amorphic state, ready for assimilation. The vortex movement assures the osmotic suction condition in preponderance over a pressure condition. Increased pressure in a blood

vessel leads to crystalline sclerotic deposits on the vascular walls. This may end in strokes through bursting of encrusted vessels.

The "toward the inside" roll of a vortex movement reduces friction on the walls of blood vessels and this motion helps cool the blood to protect it from excessive heat . It does this by perpetually changing the surface layer, thus preventing any portion of the fluid to be exposed for any length of time to the warmer outside walls. The centripetal contraction of a vortex also regulates the necessary specific density of the blood plasma.

The Blood of the Earth – Water

We know our blood is made up mostly of water. As a matter of fact, all biological systems consist mostly of water. It is obvious that water is one of the primary and most essential elements for all living processes. In the second month of gestation a human being still consists almost entirely of water and even as an old man about 60 percent of his substance is water.

Oddly enough, water has the same basic needs to maintain maximum health and rejuvenate itself that blood requires. Viktor Schauberger, an Austrian Forester called the "Water Magician" during the 1930's-1950's realized that water is the blood of the earth. The rivers, streams and underground veins of water he called the arteries and network of capillaries of our living organism earth. He taught that water is not just the chemical formula H2O, but instead is the 'first born' organic, living substance of our Universe!

Since water is a living organism it has certain metabolic needs to maintain its health. Schauberger discovered that metabolism and defined water's needs as:

1. The freedom to flow in a vortexian, spiralic movement
2. Protection from excessive pressure, light and heat
3. Exposure to oxygen and atmospheric gases through a diffusion process ONLY
4. Contact with certain elements for ionization and catalytic influence.

Meeting these needs allows water to approach an optimally cool temperature, regulate its own ph and freezing and boiling points, maintain a healthy firm surface tension, and collect and carry nutrients and an electrical potential. (See the "Wasserfaden Experiment" to measure water's electricity) Vortexian Mechanics is the study of "paths of motion", their characteristics and the result of that motion in our Universe.
